# PERFECT SUBGROUPS OF HNN EXTENSIONS 

F. C. TINSLEY (JOINT WITH CRAIG R. GUILBAULT)

## Introduction

This note includes supporting material for Guilbault's one-hour talk summarized elsewhere in these proceedings. We supply the group theory necessary to argue that Guilbault's tame ends cannot be pseudocollared. In particular, we show that certain groups (the interated Baumslag-Solitar groups) cannot have any non-trivial perfect subgroups. The absence of non-trivial perfect subgroups, in turn, eliminates the possibility of non-trivial homotopy equivalences.

In contrast, we include an example of a pseudo-collared end based on groups (the interated Adam's groups) that are somewhat similar to the Baumslag-Solitar groups. We close with a discussion of a homotopy theoretic approach to this construction.

## 1. The Groups

We use the following standard notation. We let $x^{g}=g^{-1} x g$ or the conjugation of $x$ by $g$, and let $[s, t]=s^{-1} t^{-1}$ st or the commutator of $s$ and $t$. Let $S$ be a subset of elements of a group $N$. We denote by $\left\langle s_{1}, s_{2}, \cdots ; N\right\rangle$ the subgroup of $N$ generated by $S$ where $S=\left\{s_{1}, s_{2}, \cdots\right\}$. If $N$ is omitted, then $\left\langle s_{1}, s_{2}, \cdots\right\rangle$ is the free group generated by the characters $s_{1}, s_{2}, \cdots$. If $S$ and $N$ are as above, then we denote by $n c l\left\{s_{1}, s_{2}, \cdots ; N\right\}$ the normal closure of $S$ in $N$ or the smallest normal subgroup of $N$ containing $S$.

A group $N$ is perfect if it is equal to its commutator subgroup. Symbolically, $N=[N, N]=N^{(1)}$. Equivalently, $N$ is equal to the transfinite intersection of its derived series.

The construction of the pseudo-collared end is based on the onerelator group, Adam's group:

$$
A_{1}=\left\langle a_{1}, a_{0} \mid a_{1}^{2}=a_{1}^{\left(a_{1}^{a_{0}}\right)}\right\rangle
$$

We can repeat this pattern to obtain the iterated Adam's groups, $A_{k}$, $1 \leq k<\infty$ :

$$
\left\langle a_{0}, a_{1}, \cdots, a_{k} \mid a_{1}^{2}=a_{1}^{\left(a_{1}^{a_{0}}\right)}, \underset{53}{a_{2}^{2}}=a_{2}^{\left(a_{2}^{a_{1}}\right)}, \cdots, a_{k}^{2}=a_{k}^{\left(a_{k}^{a_{k-1}}\right)}\right\rangle
$$

For each $i \geq 1, a_{i}$ is a commutator $a_{i}=\left[a_{i}, a_{i}^{a_{i-1}}\right]$.
Guilbault constructs the tame end that is not pseudo-collared using the simplest Baumslag-Solitar group:

$$
\begin{aligned}
B_{1} & =\left\langle b_{1}, b_{0} \mid b_{1}^{2}=b_{0}^{-1} b_{1} b_{0}\right\rangle \\
& =\left\langle b_{1}, b_{0} \mid b_{1}^{2}=b_{1}^{b_{0}}\right\rangle
\end{aligned}
$$

Again, we can iterate to obtain the group, $B_{k}$ :

$$
\left\langle b_{0}, b_{1}, \cdots, b_{k} \mid b_{1}^{2}=b_{1}^{b_{0}}, b_{2}^{2}=b_{2}^{b_{1}}, \ldots, b_{k}^{2}=b_{k}^{b_{k-1}}\right\rangle
$$

For each $i \geq 1, b_{i}$ is a commutator $b_{i}=\left[b_{i}, b_{i-1}\right]$.

## 2. HNN Extensions

The iterations above are each of a more general form. Given $L<K$ and $\psi: L \xrightarrow{1: 1} K$, we define the $H N N$ extension $N$

$$
\left.\langle\operatorname{gen}(K), t| \operatorname{rel}(K), \psi(l)=t^{-1} l t \text { for } l \in L\right\rangle .
$$

The extension is split if there is a retraction $r: K \rightarrow L$. The following are well-known for HNN-extensions.

## Facts:

(1) $K$ is a natural subgroup of $N$.
(2) $N$ naturally retracts onto $\langle t\rangle \cong \mathbb{Z}$, called the free part of $N$. The kernel of the retraction is $n c l\{\{K\} ; N\}$.
We also use the following well-known result about the structure of subgroups of HNN extensions:

Theorem 1 (see [KS], Theorem 6). Let $N$ be the HNN group above. If $H$ is a subgroup of $N$ that has trivial intersection with each of the conjugates of $L$, then $H$ is the free product of a free group with the intersections of $H$ with certain conjugates of $K$.

## 3. The main theorem

First, we list some basic propositions that easily follow from the definitions:

Proposition 1. If $N$ and $H$ are any groups, $\phi: N \rightarrow H$ is a homomorphism, and $P<N$ is perfect, then $\phi(P)$ is perfect.

First, a similarity between $A$ and $B$ :
Proposition 2. For $G=A, G=B$, and each $k \geq 1$, there is a surjection

$$
\gamma_{k}: G_{k} \xrightarrow[g_{k}=1]{\longrightarrow} G_{k-1}
$$

Then, two important distinctions between $A$ and $B$.
Proposition 3. The subgroup, $n c l\left\{a_{1} ; A_{1}\right\}$, of $A_{1}$ is perfect. Moreover, the subgroup, ncl $\left\{a_{1}, ; A_{k}\right\}$ of $A_{k}$ is perfect.

And, now the crucial negative result for $B_{j}$ :
Theorem 2. For $j \geq 0$, the iterated Baumslag-Solitar group $B_{j}$ has no non-trivial perfect subgroups.

Proof. We induct on $j$. The cases $(j=0)$ and $(j=1)$ are handled separately. For $j=0, B_{0}$ is abelian. For $j=1$, we observe that $B_{1}$ is one of the well-known Baumslag-Solitar groups for which the kernel of the map $\psi_{1}: B_{1} \rightarrow B_{0}$ is abelian. Then, we apply the argument used for the case $j=2$.

$$
\begin{aligned}
(j & \geq 2) \text { Let } \\
B_{j} & =\left\langle b_{0}, b_{1}, \cdots, b_{j} \mid b_{1}^{2}=b_{0}^{-1} b_{1} b_{0}, b_{2}^{2}=b_{1}^{-1} b_{2} b_{1}, \cdots, b_{j}^{2}=b_{j-1}^{-1} b_{j} b_{j-1}\right\rangle
\end{aligned}
$$

Now, $B_{j}$ now can be put in the form of the HNN group. In particular, $B_{j}=\left\langle\operatorname{gen}(K), t_{1} \mid \operatorname{rel}(K), R_{1}\right\rangle$ where

$$
K=\left\langle b_{1}, b_{2}, \cdots, b_{j} \mid b_{2}^{2}=b_{1}^{-1} b_{2} b_{1}, \cdots, b_{j}^{2}=b_{j-1}^{-1} b_{j} b_{j-1}\right\rangle,
$$

$t_{1}=b_{0}, L_{1}=\left\{b_{1} ; B_{j}\right\}, \phi_{1}\left(b_{1}\right)=b_{1}^{2}$, and $R_{1}$ is given by $b_{1}^{2}=b_{0}^{-1} b_{1} b_{0}$. The base group, $K$, obviously is isomorphic to $B_{j-1}$ with that isomorphism taking $b_{i}$ to $b_{i-1}$ for $1 \leq i \leq j-1$. Define $\psi_{j}: B_{j} \rightarrow B_{j-1}$ by adding the relation $b_{j}=1$ to the group $B_{j}$. By inspection $\psi_{j}$ is a surjective homomorphism. We assume that $B_{i}$ contains no non-trivial perfect subgroups for $i \leq j-1$ and prove that $B_{j}$ has this same property. To this end, let $P$ be a perfect subgroup of $B_{j}$. Then, $\psi_{j}(P)$ is a perfect subgroup of $B_{j-1}$. By induction, $\psi_{j}(P)=1$. Thus, $P \subset \operatorname{ker}\left(\psi_{j}\right)$. By the inductive hypothesis, $K$ has no perfect subgroups. Moreover, $b_{1} \in K$ still has infinite order in both $K$ (by induction) and $B_{j}$ (since $K$ embeds in $B_{j}$ ). Moreover, the HNN group, $B_{j}$, has the single associated cyclic subgroup, $L=<b_{1} ; B_{j}>$, with conjugation relation $b_{1}^{2}=b_{0}^{-1} b_{1} b_{0}$. Recall that $\psi_{j}: B_{j} \rightarrow B_{j-1}$ is defined by adding the relation $b_{j}=1$ to $B_{j}$. Thus, $\operatorname{ker}\left(\psi_{j}\right)=\operatorname{ncl}\left\{b_{j} ; B_{j}\right\}$.

Claim. No conjugate of $L$ non-trivially intersects $H=n c l\left\{b_{j} ; B_{j}\right\}$
Proof of Claim: If the claim is false, then $L$ itself must non-trivially intersect the normal subgroup, $n c l\left\{b_{j} ; B_{j}\right\}$. This means that $b_{1}^{m} \in$ $n c l\left\{b_{j} ; B_{j}\right\}=\operatorname{ker}\left(\psi_{j}\right)$ for some integer $m>0$. Since $j \geq 2$, then $\psi_{j}\left(b_{1}^{m}\right)=\psi_{j}\left(b_{1}\right)^{m}=b_{1}^{m}=1$ in $B_{j-1}$, ie, $b_{1}$ has finite order in $B_{j-1}$. This contradicts our observations above.

We continue with the proof of Theorem 2. Recall that $P$ is a perfect subgroup of $\operatorname{ker}\left(\psi_{j}\right)$. It must also enjoy the property of trivial intersection with each conjugate of $L$. We now apply Theorem 1 to the subgroup $P$ to conclude that $P$ is a free product where each factor is either free or equal to $P \cap g^{-1} K g$ for some $g \in B_{j}$. Now, $P$ projects naturally onto each of these factors so each factor is perfect. However, non-trivial free groups are not perfect. Moreover, by induction, $K$ (or equivalently $g^{-1} \mathrm{Kg}$ ) contains no non-trivial perfect subgroups. Thus, any subgroup, $P \cap g^{-1} K g$, is trivial. Consequently, $P$ must be trivial. This completes the proof of Theorem 2.

## 4. Geometry and homotopy theory

We begin this section by emphasizing the similarities between $A$ and $B$. We let $G$ stand for either $A$ or $B, g$ stand respectively for either a or $b$, and $w\left(g_{j}\right)$ stand respectively for either $g_{j}^{g_{j-1}}$ or $g_{j-1}$. Then,

$$
G_{k}=\left\langle g_{0}, g_{1}, \cdots, g_{k} \mid g_{1}^{2}=g_{1}^{w\left(g_{1}\right)}, g_{2}^{2}=g_{2}^{w\left(g_{2}\right)}, \vdots, g_{k}^{2}=g_{k}^{w\left(g_{k}\right)}\right\rangle
$$

represents either $A_{k}$ or $B_{k}$. For each $i \geq 1, g_{i}$ is a commutator $g_{i}=$ $\left[g_{i}, w\left(g_{i}\right)\right]$. We can summarize the relationship as follows:

SIMILARITES AND DIFFERENCES (G equals A or B)

| Properties | Adam's | Baum.- <br> Solitar |
| :---: | :---: | :---: |
| 1 Relator Group | $\sqrt{ }$ | $\sqrt{ }$ |
| $G^{(1)}=n c l\left(g_{1} ; G\right)$ | $\sqrt{ }$ | $\sqrt{ }$ |
| Perfect $G^{(1)}$ | $\sqrt{ }$ | $\times$ |
| Abelian $G^{(1)}$ | $\times$ | $\sqrt{ }$ |
| Abelianizes to $\mathbb{Z}$ | $\sqrt{ }$ | $\sqrt{ }$ |
| $\mathbb{Z} \xrightarrow[\text { split }]{H N N} \xrightarrow[\text { split }]{H} G$ | $\sqrt{ }$ | $\sqrt{ }$ |

Moreover, $g_{k}$ is the commutator of itself with another element, $g=$ $w\left(g_{k}\right)$, of $G_{k}$. So, if $G_{k}$ is the fundamental group of a high-dimensional manifold, $M_{k}$, then $g_{k}$ bounds a disk with one handle in $M_{k}$ where one of the handle curves is homotopic (rel basepoint) to $g_{k}$. We let this be the meridianal handle curve:

We can attach a two handle to $M_{k}$ along $g_{k}$. Then, the disk with handle and three copies of the core of the two handle form a 2 -sphere, $S_{k}^{2}$, along which a three handle can be attached.

Note that this $S_{k}^{2}$ will algebraically cancel the 2-disk since it will be attached twice with one sign and once with the opposite sign. As a result the manifold, $N_{k}$, resulting from attaching these two handles

Figure 1

to $M_{k}$, will have the same homology as $M_{k}$. In fact, we obtain a cobordism, $\left(W_{k}, M_{k}, N_{k}\right)$, where the inclusion $N_{k} \rightarrow W_{k}$ induces an equivalence of homology groups.

This inclusion also induces an isomorphism on fundamental groups: $\pi_{1}\left(N_{k}\right) \xrightarrow{\cong} \pi_{1}\left(W_{k}\right) \cong G_{k-1}$. One might conclude that $N_{k} \rightarrow W_{k}$ induces a homotopy equivalence. However, this is the case only for Adams group.

The Hurewicz Theorem is needed to argue from data about homology to conclusions about homotopy. It requires simply connected spaces. Thus, we must pass to the universal covers, $\widetilde{W}_{k}$ and $\widetilde{N}_{k}$, of the manifolds, $W_{k}$ and $N_{k}$ and the cover, $\widehat{M}_{k}$, of the manifold, $M_{k}$, that corresponds to the $\pi_{1}$-kernel of the induced map, $\pi_{1}\left(M_{k}\right) \rightarrow \pi_{1}\left(W_{k}\right)$.

The key becomes the longitudinal curve, $g$, on the disk-with-handle (shown below in bold).

It is quite different for the $A_{k}$ and $B_{k}$. For Adams group, $g=$ $a_{i}^{a_{i-1}}=a_{i-1}^{-1} a_{i} a_{i-1}$ while for the Baumslag-Solitar group, $g=a_{i-1}$. In

Figure 3
the first case, the element, $g=a_{i-1}^{-1} a_{i} a_{i-1}$, is a conjugate of $a_{i}$, and, in particular, lifts as a loop to $\hat{M}$. Consequently, the same cancellation in homology occurs in the universal cover as in the space itself and, thus, homology equivalences will yield a homotopy equivalence. In the second case, the conjugating element, $b_{i-1}$, lifts as an $\operatorname{arc}$ to $\hat{M}$. Thus, the two copies of the core of the 2-handle that cancelled as elements of $H_{2}(W, M)$ represent distinct generators of $H_{2}(\tilde{W}, \hat{M})$ that have different signs but, in fact, do not cancel.
